

Abstract—The purpose of this study was to determine if there were differences in the prevalence of musculoskeletal disorders among different types of workers. The study included 600 male employees from a large manufacturing company who had been employed for at least one year. They completed a questionnaire about their work activities and health status. The results showed that the prevalence of musculoskeletal disorders was higher among workers in the production department than among those in the maintenance department. This suggests that the type of work may influence the risk of developing musculoskeletal disorders.
